

TNB – Combined metrics

Content:

- LISAS, IES and RCS calculations for each subtest divided by age [↗](#)
- Box plots for each metric with each subtest [↗](#)
- Correlation matrices of each of the metrics between subtests [↗](#)

To make the visualization easier, the RT and Accuracy slides from the previous presentation were also included.

The first slides include important considerations to better understand the analysis.

Bin Scores

I understood from Huges et al. (2014) and Vandierendonck (2017) that bin scores are used in the task-switching paradigm. Since, as I understand it, the TNB is not a task-switching test, I could not calculate bin scores. Even though I tried, I found some variables required to calculate this metric impossible to obtain. For example:

“Its calculation, as defined in Hughes et al. (2014), assumes that there are two conditions, basically a control and an experimental condition (e.g., task repetition and task switch trials to estimate the task switch cost)”

Vandierendonck (2017)

Does our test have control conditions?

LISAS

“If the number of observations per condition is too small, more stable estimates of the standard deviation can be obtained by grouping conditions, or by taking the standard deviation per subject. In the present paper, the standard deviations are calculated per condition”
Vandierendonck (2018)

I **did not** do this because:

- 10 observations/condition seemed ok
- I did not find a proper grouping strategy (I can easily do this if we find one)

“General” and “When accurate”

*“ RT_j is the participant’s mean RT in condition j , ..., S_{RT} is the participant’s **overall** RT standard deviation”*

Vandierendonck (2017)

*“the average **correct** RT (RT_c)”*

*“ S_{RT} refers to the standard deviation of the **correct** RTs”*

Vandierendonck (2018)

Because of this difference, you will find “General” and “When accurate” in LISAS plots. The same happened with IES.
